## LECTURE 3

## Chapter 5

## RISK RETURN -

## Return

- Traditionally, when you define return you refer to a bank savings account (risk free) plus a risky portfolio of US stocks. Today, investors have access to a variety of asset classes and financial engineered investments
- The Book "The Quants" by Scott Peterson - financial engineering - achieving the ALPHA.

## HPR $=($ Ending Price - Beg. Price + Div $) /$ Beg. Price

## Example:

Current Price $=\$ 100$, expected price to increase to $\$ 110$ in a year. Within the year you are expected to receive $\$ 4$ dividend, therefore the $H P R=(110-100+4) / \$ 100=14 \%$

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

Professor Chris Droussiotis' Notes

Measuring Return over a multiple periods
ARITHMETIC AVERAGE (Sum of Quarters)
GEOMETRIC AVERAGE (Single per Quarter - cumulative + compounding)

|  | 0 | 1 | 2 | 3 | 4 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| HPR $\%$ |  | 10 | 25 | -20 | 25 |

## Arithmetic:

$(10+25-20+25) / 4=10 \%$

## Geometric:

$(1+0.10) *(1+0.25) *(1-0.20) *(1+0.25)=(1+\mathrm{r}) \wedge 4$
$\mathrm{r}=[(1+0.10) *(1+0.25) *(1-0.20) *(1+0.25)] \wedge 1 / 4-1$
$\left(1.1 * 1.25^{*} .80^{*} 1.25\right)^{\wedge} 1 / 4-1=$
$1.375^{\wedge} 1 / 4-1=8.29 \%$

## Dollar Weighted Return

|  | 0 <br> (initial) | 1 | 2 | 3 | 4 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Net CF $(\$)$ | -1 | -0.1 | -0.5 | 0.8 | 1.0 |

$1=+\left(-0.1 /(1+\mathrm{IRR})+\left(-0.5 /(1+\mathrm{IRR})^{\wedge} 2+\left(0.8 /(1+\mathrm{IRR})^{\wedge} 3+\left(1.0 /(1+\mathrm{IRR})^{\wedge} 4\right)\right.\right.\right.$
Excel

| IRR | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $4.17 \%$ | -1 | -0.1 | -0.5 | 0.8 | 1 |

$=$ IRR (initial investment, cash flows)
$=4.17 \%$

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

## Professor Chris Droussiotis' Notes

Conventions for Quoting Rates of Return: Return on Assets with Regular Cash Flow (Mortgage, bonds - semi-annual coupon)

APR (Annual Percentage Rates) - using simple interest approach

$$
\mathbf{A P R}=\text { per period rate } * \text { Periods per Year }
$$

EAR (Effective Annual Rate)

$$
1-\operatorname{EAR}=(1+\text { Rate per period })^{\wedge} \mathrm{n}=\left[(1+(\mathrm{APR} / \mathrm{n}))^{\wedge} \mathrm{n}\right.
$$

$$
\mathrm{APR}=(1+\mathrm{EAR})^{\wedge} 1 / \mathrm{n}-1 * \mathrm{n}
$$

For continuous compounding, $1+\mathrm{EAR}=\mathrm{e}^{\wedge} \mathrm{APR}$ or $\mathrm{APR}=\ln (1+\mathrm{EAR})$

$$
\mathbf{E A R}=(1+\text { Per period Rate })^{\wedge \text { number periods }}-1
$$

## Example:

Suppose we buy T-Bills maturing in one month for $\$ 9,900$ (on maturity you collect the Face Value $\$ 10,000$ ).

HPR $=($ Cash Income + Price Change $) /$ Initial Price
$\mathrm{HPR}=100 / 9,900=0.0101=1.01 \%$
$\mathrm{APR}=1.01 \% * 12($ annualized $)=12.12 \%$
$\mathrm{EAR} \rightarrow 1+\mathrm{EAR}=(1.0101)^{\wedge} 12=1.1282$
$\mathrm{EAR}=1.1282-1=.1282=\underline{\mathbf{1 2 . 8 2} \%}$

## RISK AND RETURN PREMIUMS

## HOW DO WE QUANTIFY RISK?????

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

Professor Chris Droussiotis' Notes

Scenarios Analysis and Probability Distributions

|  | Scenarios | Probability | HPR | WAHPR <br> (probability*HPR) |
| :--- | :---: | :---: | :---: | :---: |
| Boom Growth | 1 | 0.25 | $44 \%$ | $11.00 \%$ |
| Normal Growth | 2 | 0.5 | $14 \%$ | $7.00 \%$ |
| Recession Growth | 3 | 0.25 | $-16 \%$ | $-4.00 \%$ |

## HOW DO WE QUANTIFY THE UNCERTAINTY OF INVESTMENT???

To summarize risk with a single number we find VARIANCE, the expected value of the squared Deviation for the mean, first. (I.e. the expected value of the squared "surprise": across scenarios.)

$$
\operatorname{Var} .(r)=\sigma^{\wedge} 2=\sum p(s)[r(s)-E(r))^{\wedge} 2
$$

## VARIANCE-DEFINITION

The Variance (which is the square of the standard deviation, ie: $\sigma^{2}$ ) is defined as:

## The average of the squared differences from the Mean.

In other words, follow these steps:

1. Work out the Mean (the simple average of the numbers)
2. Now, for each number subtract the Mean and then square the result (the squared difference).
3. Then work out the average of those squared differences.

- Squaring each difference makes them all positive numbers (to avoid negatives reducing the Variance)
- And it also makes the bigger differences stand out. For example $100^{2}=10,000$ is a lot bigger than $50^{2}=2,500$.
- But squaring them makes the final answer really big, and so un-squaring the Variance (by taking the square root) makes the Standard Deviation a much more useful number.

Variance $=$ Squared Sigma
STANDARD DEVLATION DEFINITION: The Standard Deviation ( $\sigma$ ) is a measure of how spreads out numbers are. (Note: Deviation just means how far from the normal). So, using the

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

## Professor Chris Droussiotis' Notes

Standard Deviation we have a "standard" way of knowing what is normal, and what is extra large or extra small.

|  | Scenarios | Probability | HPR | WAHPR (probability*HPR) | Variance [probability*(HPRsum of WAHPR) ${ }^{\wedge}$ 2] |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Boom Growth | 1 | 0.25 | 44\% | 11.00\% | 225.00 |
| Normal Growth | 2 | 0.5 | 14\% | 7.00\% | 0.00 |
| Recession Growth | 3 | 0.25 | -16\% | -4.00\% | 225.00 |
| $14.00 \%$ 450.00 <br> St. Dev $=$ $21.21 \%$ |  |  |  |  |  |
|  |  |  |  |  |  |

$\operatorname{SD}(\mathrm{r})=\sigma=\sqrt{ } \operatorname{Var}(\mathrm{r})$
$E(r)=(0.25 * 44 \%)+(0.50 * 14 \%)+(0.25 *-16 \%)=\underline{\mathbf{1 4} \%}$
Sigma $\wedge 2=0.25(44-14)^{\wedge} 2+0.50(14-14)^{\wedge} 2+0.25(-16-14)^{\wedge} 2=450$
And so the $S D$ sigma $=\sqrt{ } 450=\underline{\mathbf{2 1 . 2 1 \%}}$

## EXAMPLE - table 5.2

| Current Price $=$ | $23.50$ <br> Scenarios |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Probability | End of yr Price | Dividends | HPR \% | WAHPR | Variance |
| High Growth | 1 | 0.35 | \$ 35.00 | \$ 4.40 | 67.66 | 23.68 | 591.41 |
| Normal Growth | 2 | 0.30 | \$ 27.00 | \$ 4.00 | 31.91 | 9.57 | 8.62 |
| No Growth | 3 | 0.35 | \$ 15.00 | \$ 4.00 | (19.15) | (6.70) | 731.04 |

| HPR $=($ End of the year Price - Current Price + Div $) /($ Current Price $)$ | $E(r)=26.55$ 1,331.07 |
| ---: | ---: |
| StDev $=36.48$ |  |

Standard Deviation $=\mathrm{Sq} \mathrm{Rt}$ of V
Variance $=0.35^{*}(67.66-26.55)^{\wedge} 2+.30^{*}(31.91-26.55)^{\wedge} 2+.35^{*}(-19.5-26.55)^{\wedge} 2$

# BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE 

Professor Chris Droussiotis' Notes

## RISK PREMIUM Vs RISK AVERSION (Risk Appetite)

We measure the "Reward" or the difference between the expanded HPR or the Index stock fund and the risk - free rate

HPR - Risk Free Rate $=$ Premium
$14 \%-6 \%=8 \%$
VOLATILITY vs RETURN - Relationship
Sharpe Ratio:
Risk Premium over the Standard Deviation of portfolio excess return

$$
(E(r p)-r f) / \sigma
$$

$8 \% / 20 \%=0.4 \mathrm{x}$. A higher Sharpe ratio indicates a better reward per unit of volatility, in other words, a more efficient portfolio

Sharpe Ratio is more useful for ranking portfolios - it is not valid for individual assets is useful across Asset Classes.

## HISTORICAL RECORD OF RETURNS - TAbLE 5.3 - Panel B

To calculate average returns and standard deviations from historical data, let's compute these statistics for the returns on the S\&P 500 portfolio using five years of data from the table (5.4)

Example 5.4

| Year | ROR | Deviation <br> from <br> Average <br> Return | Deviation From Avg <br> return Squared ( 2 ) |
| :---: | :---: | ---: | :---: |
| 1 | $16.90 \%$ | $0.22 \%$ | 0.05 |
| 2 | $31.30 \%$ | $14.62 \%$ | 213.74 |
| 3 | $-3.20 \%$ | $-19.88 \%$ | 395.21 |
| 4 | $30.70 \%$ | $14.02 \%$ | 196.56 |
| 5 | $7.70 \%$ | $-8.98 \%$ | 80.64 |
|  |  |  |  |
|  |  |  |  |

| observations $(n)=$ | 5 |
| :--- | :--- |
| Average $\mathrm{ROR}=$ $16.68 \%$ $=83.40 / 5$ <br> Var $=886.21 /(5-1)=$ 221.552 $=886.21 /(5-1)$ <br> Standard Deviation $=$ $14.88 \%$ $=$ SQRT 221.552 |  |

INFLATION, NOMINAL AND REAL RATES OF RETURN
Nominal Rate of Return $(R)=10 \%$
Inflation (i) $=6.0 \%$
$r=R-i$
Real Rate of Return (r) (Approximation) $=4.0 \%$
Real Rate of Return (Exact) $=\mathrm{r}=(\mathrm{R}-\mathrm{i}) /(1+\mathrm{i})$

## Example

Invest in one-year CD for $8.0 \%$. Inflation is $5.0 \%$. Find the approximate and exact Real Rate of Return:

Approximate $r=8.00 \%-5.00 \%=3.00 \%$
Exact $\mathrm{r}=(8.00 \%-5.00 \%) /(1+5.00 \%)=2.86 \%$

## EQUILIBRIUM NOMINAL RATE OF INTEREST

Fisher Equation ........ $\mathrm{R}=\mathrm{r}+\mathrm{E}(\mathrm{i}) \ldots \ldots .$. Nominal rate ought to increase one for one with increase of expected inflation

## ASSET ALLOCATION ACROSS RISKY AND RISK FREE PORTFOLIOS

 Percentage acrossProfessor Chris Droussiotis' Notes

## Total Portfolio $=300,000$

| Cash | 90,000 | $30 \%$ |
| :--- | ---: | ---: |
| Stocks | 210,000 <br> Total300,000 |  |

| Stocks |  | of total Portfolio | of total Stocks |
| :--- | ---: | ---: | ---: |
| S\&P 500 Index | 113,400 | $37.800 \%$ | $54.000 \%$ |
| Fidelity Invest | 96,600 | $32.200 \%$ | $46.000 \%$ |
|  | 210,000 | $70.000 \%$ | $100.000 \%$ |
| Cash | 90,000 | $30.000 \%$ |  |
|  | 300,000 | $100.000 \%$ |  |

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

## Professor Chris Droussiotis' Notes

## Portfolio Expected Return and Risk

+ Optimal Risky Portfolio (P)
+ Proportion of the Investment budget ( Y ) to be allocated to it.
+ The remaining portion (1-Y) is to be invested is the Risk-free Asset (rf)
+ Actual risk rate of return by rp on $P$ by $E(r p)$ and Standard Deviation $\sigma p$
+ The rate on risk-free asset is denoted a rf
+ The portfolio return is $\mathrm{E}(\mathrm{rc})$

$$
\begin{aligned}
\mathrm{E}(\mathrm{rp}) & = & 15 \% \\
\sigma & & 22 \% \\
\mathrm{Rf} & = & 7 \% \\
\mathrm{E}(\mathrm{rp})-\mathrm{rf} & = & 8 \%
\end{aligned}
$$

## Let's start with two extreme cases

1. If $y=1$ (all of the portfolio in the risk asset)

$$
\begin{aligned}
E(\mathrm{rp})= & 15 \% \\
\sigma p= & 22 \%
\end{aligned}
$$

2. If $y=0$ (none of the portfolio in the risk asset)

$$
\begin{aligned}
\mathrm{rf}= & 7 \% \\
\sigma \mathrm{p}= & 0 \%
\end{aligned}
$$

$$
\begin{aligned}
& E(r \mathrm{c})=1.5 * 7 \%+0.5 * 15 \%=11 \% \\
& E(\mathrm{rc})-\mathrm{rf}=\mathrm{y}[\mathrm{E}(\mathrm{rp})-\mathrm{rf}] \\
& \quad \sigma c=y \sigma p
\end{aligned}
$$

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

## Professor Chris Droussiotis' Notes

## The Capital Allocation Line (CAL)

Different values of Y (risky portfolio)
The slope ( s ) of the CAL equals the increase in expected return that an investor can obtain per unit of additional standard deviation.

THE REWARD-TO-VOLATILITY RATIO (Sharpe Ratio)

|  | Exp. Return | Risk Premium | Standard Dev. | Sharpe Ratio |
| :--- | :---: | :---: | :---: | :---: |
| Portfolio P. | $15 \%$ | $8 \%$ | $22 \%$ | $8 / 22=0.36$ |
| Portfolio C. | $11 \%$ | $4 \%$ | $11 \%$ | $4 / 11=0.36$ |

Plot on CAL the Sharpe Ratio is the same

$\mathrm{Rf}=7 \% \ldots$. If the investor can borrow at (risk free) rate of $\mathrm{rf}=7.0 \%$, then he/she can construct a complete portfolio that plot on the CAL line to the right of P where $\mathrm{y}>1$

Example:
Originally have $\$ 300,000$ - borrows additional $\$ 120,000=\$ 420,000$ invested at y risk This is a levered position in risky assets
$y=420,000 / 300,000=1.4 x$ and $1-y=-0.4$, reflecting a short position in the risk-free assets - a borrowing position $=7.0 \%$

The portfolio rate of return is

$$
\mathrm{E}(\mathrm{rc})=7+(1.4 * 8)=18.2 \%
$$

## BARUCH COLLEGE - DEPARTMENT OF ECONOMICS \& FINANCE

Professor Chris Droussiotis' Notes
Your income $=\$ 63,000(15 \%$ of $\$ 420,000)$ and pay $\$ 8,400(7 \%$ of 120,000$)$ interest
$\$ 63,000-8,400=54,600$
$54,600 / 300,000=18.2 \%$
Sharpe Ratio:

$$
\sigma_{\mathrm{i}}=1.4 * 22=30.8
$$

$\mathrm{S}=(\mathrm{E}(\mathrm{ri})-\mathrm{rf}) / \sigma \mathrm{i}=(18.2-7.0) / 30.8=11.2 / 30.8=0.36$
