Chapter 1 RISK & RETURN ANALYSIS

This chapter will cover the basic concepts of risk and return and what constitutes a satisfactory investment portfolio. The chapter will also examine return expectation for specific asset classes such as stocks and bonds and walk through the reader on how to use the two different analytical approaches to determine the risk return balance. These methods being fundamental and technical analysis.

Learning Objectives

After reading this chapter, students will be able to:

- Compute various measures to calculate the historical and expected returns on many asset classes such as equities and bonds.
- Quantify the risk on these asset classes by calculating the variance and standard deviation.
- Understand how to measure past performance of stocks and bonds using both historical analysis and scenario analysis to determine the expected risk/return going forward.
- Construct a portfolio of investments consisting of stocks, bonds and risk-free investments such as cash, money market or treasury bills and the impact of diversification.
- Understand portfolio optimization and efficiency based on asset allocation between stock, bonds and cash.

Rates of Return Overview

[Insert boxed text here

AUTHOR'S NOTES:

A joke that I heard many years ago makes a perfect introduction to investment return expectation and it goes like this: John woke up one morning and looked at the clock and it was 7:07am. Then he looked at the calendar and the day was July 7 or 7/7. He noticed that the 7s could be the theme of the day. As he was running out of the door he stopped at his mailbox and he opened an envelope with his weekly paycheck that had a check for \$777.77. As he was crossing the road, he almost got hit by a car that stopped inches short of his body. The car's license number was GGG 777 – very strange he moans considering that G is also the 7th letter of the alphabet. He looked up and saw that the seven bus was approaching the station. So, he had to get on it. He was sure that this was a sign. He asked the bus driver when the next station is, and the bus driver said: "the seventh station". He said to himself: "I need to get off the bus at the next station". After he got off the bus he looked up and saw a building in front of him: "77 on 7th Avenue" posted on top of the door. He walked in to the building as he was sure by now that this is a sign. In the lobby of the building there was an Off-Track Betting (OTB) store where patrons can bet on horse races without being at the racetrack. John walked in and asked when the next race is. He was told that the next race is the 7th race and he had exactly 7 minutes before post time. He then asked how many horses race in this 7th race. Seven horses, someone shouted. He then asked what are the odds that the horse with number 7 will win. "Don't bother" somebody shouted, "this is a long shot… 77 to 1 to win". John thought to himself: "this is it". He approached the betting window and said: "here is my paycheck of \$777.77. Put it all for 7 to win…. I am feeling it he shouted". Of course, with 77 to 1 odd his payoff will be huge making approximately \$60,000 on \$777.77 bet if the 7 horse wins. The race was over……… and the number 7 horse came in 7th. You see this is a funny way of explaining the investment expectation based on trends – of course this bet or investment is all based on behavioral return expectation which is very difficult to predict since there was no mathematical basis. Such behavioral analysis which in many cases dictates why someone buys or sells the stock won't be covered in this chapter. They are many books written on behavioral finance that discusses various interesting observations that challenges the traditional analytical tools of risk and return analysis. The other measurements of risk & return expectations that this chapter and this unit will cover are through fundamental and technical analyses.

KEY TAKEAWAYS:

- Before investing, the investor needs to consider the following four factors:
 - 1. measure the expected return
 - 2. quantify the risk;
 - 3. how to allocate the investments; and
 - 4. time or determine the exit strategy or realization of the investment.
- To determine the return expectation or predict the investment payoff, the analyst could use fundamental analysis, technical analysis or behavioral analysis. The chapter will focus on the first two.
- By allocating the investments across different asset classes including stocks, bonds and cash, the investors can diversify their risk and achieve portfolio efficiency which is the point where you achieve the highest possible return at the lowest possible risk.
- The analyst can also determine the future risk/return expectation by analyzing the historical trends and apply various economic scenarios based on probability outcomes such as the expected performance under recessionary or economic boom environment.

End boxed text here]

Before you invest your money in any securities or any businesses, it's extremely important to consider and must measure the following four factors:

- 1. Return Expectation
- 2. Risk
- 3. Allocation
- 4. Time

All these are essential to build investment expectation. The investor needs to determine return expectation first. Without any expectations the investor should not proceed with the investment.

The expectation comes with risk appetite of the individual investor, but the basic standard expectation needs to be set before the investor makes and adjustments based on the risk that he or she is willing to take. The basic premise of course is that the higher the risk the higher the return expectation. This and the following chapters will be discussing this relationship in depth. We will examine a possibility that when the investor allocates his/her investments across different assets will not only diversify the risk but can also achieve efficiency or attempt to better balance the risk with the return. One of the most important components of achieving this measurement is to have an exit strategy or set the time when the investor can realize the investment.

Return and Return Expectation

Objective of Return and Return Expectation

As discussed previously, it is essential to measure the historical returns of a particular asset class and then set an expectation going forward based on various methods that we will examine in this section. The return analysis objectives are as follows:

- To compare to historical trends of this particular investment and project the trend going forward and adjust such trend based on views for driving such investment
- To compare to other asset classes and/or the market, and/or the risk-free rate.
- $\circ~$ To compare to last year's expectations continue to test the performance versus expectation

If all three objectives are met, then the assessment is completed. For example, just giving a rate of return number like 10% by its self is not enough. Though 10% return in a year seems like a good return, but if it was achieved in April of 1979, for example, that rate of return would have been terrible since the risk-free 3-month treasury rate and inflation were 9.8% and 11.35% respectively.

Rates of Return – Holding Period Return (HPR)

The first basic measurement of return does not consider the time that length of time that which the return was achieved is the Holding Period Return (HPR). HPR is focused on what the net return over the investment life. It measures the rate of return from the time the investor initiated the investment until the investment was realized – basically the rate of return for the holding period whether is one month or 5 years. The ratio in its most basic form is:

$$HPR = \frac{CF}{I}$$

Where CF is the Cash Flow (inflow and outflow) during the investment period and I is the initial investment. For example, if an investor buys the stock for \$100 and sells it for \$120 and during the investment he or she received \$2 dividend then the cash flow on the numerator will be \$120 of proceeds for selling the stock plus \$2 of cash dividend received (cash inflow) minus the initial investment of \$100 (cash outflow) the net cash flow will be \$22 (\$120 + \$2 - \$100). The HPR will

be calculated by dividing the net cash flow of \$22 by the initial investment of \$100 resulting to a 22% return:

$$\frac{(120 - 100 + 2)}{100} = \frac{22}{100} = 0.22 = 22\%$$

For a quick analysis of expected return, the HPR ratio which represents the relationship between cash flow to the initial investment can be found in many applications on various asset classes. For example, let's assume the investor is interested in buying a bond that has an 8% per year coupon rate or annual interest income of \$80 on a \$1,000 bond and the secondary market price of the bond is 95% of par or \$950. To calculate the expected return or the current yield (CY) in bond "talk" the numerator of \$80 representing the annual expected payment or cash flow and the denominator of \$950 representing the purchase price of the bond or initial investment will calculate the expected annual return of 8.42%:

$$CY = \frac{CF}{I} = \frac{Annual\ Coupon\ Payment}{Market\ Price\ of\ the\ Bond} = \frac{80}{950} = 0.0842 = 8.42\%$$

In many cases an expected return (discussed in depth later) that the investor sets as a target before making the investment determines the initial investment needed to achieve the expected cash flow. Using the bond example above were the annual coupon payment of \$80 is already set based on the bond agreement (indenture) but in this case the investor desires a 10.0% return based on new measured risk assessment of this bond, then to achieve 10.0% the numerator will be \$80 divided by the expected return of 0.10 or 10.0% calculating the initial investment needed \$800.00 by solving for Investment (I):

since
$$CY = \frac{CF}{I}$$
, then $CF = (CY)$. (I) and $I = \frac{CF}{CY} = \frac{80}{.10} = 800.00

This relationship between cash flow, investment, return and time are the basic variables calculating "Time Value of Money" discussed in many finance text books where the cash flow is the expected cash flow to be received in the future or future value (FV) minus the investment, the investment representing today's investment or present value (PV) and return or expected return is the interest rate (i) at a set time (t). Showing below how this ratio of HPR can translate to the concept of "Time Value of Money":

$$HPR = \frac{CF}{I} \text{ or } i = \frac{(FV - PV)}{PV} \text{ or } i = \frac{FV}{PV} - \frac{PV}{PV} \text{ or } i = \frac{FV}{PV} - 1$$

then present value (PV) is

$$PV = \frac{FV}{(1+i)}$$
 for in one year

or
$$PV = \frac{FV}{(1+i)^t}$$
 in future year t

and to calculate future value (FV)

$$FV = PV (1 + i)^{t}$$

[Insert boxed text here

Excel formulas for Present Value, Future Value and Rate of Return:

= PV (rate, years, future value) =FV (rate, years, present value) =Rate (years, future value, -present value)

End boxed text here]

When trying to calculate the annual rate instead of the total rate of return for the entire investment hold period, then this rate is referred to as the Internal Rate of Return or IRR covered in the next section below.

Rates of Return – Annual Rate of Return (ROR) and Internal Rate of Return (IRR)

The concept of "Time Value of Money" is mostly used for calculating the annual rate of return as the basis of comparing such return to other years, or to the risk-free rate to establish the risk premium – explained in later chapters. The relationship between todays' investment to future expectation for given years will result to an annual rate of return.

Starting with the basic time value of money formula of Present Value, the formula is:

$$PV = \frac{FV}{(1+i)^t}$$
 in future year t

where it calculates the initial investment needed to achieve at set future payoff in year "t" at the annual rate of return (ROR) or "i". For example, what do you need to invest today to receive \$100 in 5 years at 5% return per year? Based on the calculation below, you need to invest \$78.35:

$$pv = \frac{\$100}{(1+0.05)^5} = \frac{100}{1.2763} = \$78.35$$

If we know what we need to invest today at an annual rate "i", and we are trying to calculate what the investment will be "t" years, then the formula is:

$$FV = PV (1 + i)^t$$

For example, if you invest \$100 today for 5 years and expect 5% return per year, you investment will be calculated to grow to \$127.63:

$$Fv = \$100(1 + 0.05)^5 = \$100(1.2763) = \$127.63$$

To then reverse this formula to calculate the annual rate of return (ROR). The formula is:

$$(1+i)^t = \frac{FV}{PV}$$
, then $i = \sqrt[t]{\frac{FV}{PV}} - 1$

For example, if you invest \$100 today and expect is 5 year a payoff of \$127.63 what is the rate of return per year? The calculation below shows 5.0% annual return:

$$i=5127.63100i = \sqrt[5]{\frac{127.63}{100}} - 1 = 1.05 - 1 = 0.05 = 5\%$$

For an investment that the investor who receives annual cash flows during the investment period, the ROR calculation is a little more challenging than a one-time payment in the future. If the cash flows from the investment are the exact same amount for every year then the annual cash flows over the investment represent the annual return including original investment amount – similar to a bond investment that the investor receives annual or semi-annual fixed payments and a one-time principal payment at maturity of the bonds or early repayment (sometimes refer to as redemption).

For example, if we invest \$100 to an investment that pays \$5 fixed per year for 5 years plus receiving the initial investment of \$100 in year 5, then the annual (ROR) will be 5%.

The more challenging calculation is if the payment is different every year, so the annual rate of return must be weighted based on size and the year paid. This type of rate return method is the Internal Rate of Return. Its challenging because each year the investment would have different payoffs and sometimes negative numbers. The best approach to calculate the IRR is using spreadsheet analysis. The formula that will be used throughout this book is =IRR (CF₀, CF₁, CF₂, CF₃...,CF_t).

Figure 1.1

Rates of Return – Average Annual Rate of Return

The average annual rate of return can be calculated by looking at 5 to 10 years of historical returns and averaging them to represent the annual return. It gives the investor an indication what to expect on an average. This method is used for comparing to other investments calculated the same way and by taking this number to the next level of assessment how volatile in the return as compared to the average on a given year. We will examine relationship between the rate of return and volatility which measure the risk of such investment. They are two methods of calculating the risk/return: Historical and Scenario Analysis method.

Historical Method:

The most commonly used assessment of risk and return is to look at historical information prices for stocks or bonds or any other asset classes. Though, not perfect, the historical average shows how the investment perform through the years that includes all the high points, the low points, positive and negative points. The deviation from the average, called standard deviation represents how risky the return could be so when two portfolios have the same average return, the one that is less risky is the one with the lower standard deviation. Figure 1.2 shows that both 10-year average return for portfolios A and B is 9.92% but Portfolio B is slightly riskier with standard deviation of 14.7% versus 13.62% of Portfolio A. In this and follow-on chapters we will examine closer this relationship and how we can compare this to the market or other asset classes.

HISTORICAL RETURN ANALYSIS

Scenario Analysis Method:

The previous section goes over the calculation of historical average returns, variance and standard deviation. This section will calculate the expected return, variance and standard deviation when the information we are using is adjusted based on the probability of various economic scenarios. The aim is to examine that effect of these forces on the performance of a given portfolio. This method will then be used to recalculate the expected return, variance and standard deviation representing the risk, when two or more asset classes are added to an all equity portfolio. Depending on the correlation between the performance of different asset classes such as stocks and bonds, the analysis should demonstrate that the portfolio can achieve both efficiency and optimization. The efficiency, called efficient frontier, which is at the highest possible return with the lowest possible risk could be achieved by trading partially out of stocks into bonds and vice versa. After the efficiency is achieved, then the portfolio manager will look to optimize the portfolio. The optimization can be achieved by moving from the efficiency position to a position where the analyst is seeking additional return with minimum additional risk to to the point that the risk will catch up to the return. This optimization measured by a ratio, called Sharpe Ratio, will be described in this chapter and more detailed in the following chapters that describe the Portfolio Analysis.

Let's assume that we examined a given stock portfolio and determined the different holding period returns achieved during different economic cycles including recession, boom and normal years. Figure 1.3 below shows that during the recession, the stock portfolio showed 12% negative return, during normal years, positive 14% and boom years, positive 28%. Using scenario analysis, the average return is calculated based on the probability expectation. In other words, let's assume we asked 100 analysts what they believe the next year will bring and from our survey, 25 of them said that they expect a recession, 45 of them expect that the economy will stay at a normal stage and the remaining 30 analysts expect that we will have a boom year. We categorize their response as the probability to determine the weighted average return. Figure 1.3 shows that the expected return is calculated to be 11.70%. The variance and standard deviation using these probabilities are calculated at 222.51% or 2.225x and 14.92%, respectively.

				Stocks (s	5)

					SD =	14.92 %

SCENARIO PERFROMANCE ANALYSIS

```
Figure 1.3
```

Let's assume that we also looked at a different portfolio that includes only bonds. Figure 1.4 below shows that the bond portfolio during the same economic periods the historical return during the recession was 14.0%, during normal years, 5% and during boom years, -5.0%. Just eyeballing the differences with the stocks portfolio during this year we can easily see that the returns for the recession and boom years are moving in opposite direction where the stocks are showing positive return, the bonds show negative. We will later discuss that important relationship called correlation. Figure 1.4 shows that the expected average return using the same probability numbers as the equity is 4.25%. The variance and standard deviation is calculated at 67.75% or 0.677x and 8.23%, respectively.

SCENARIO PERFROMANCE ANALYSIS

Figure 1.4

Return, Return Expectation and Allocation

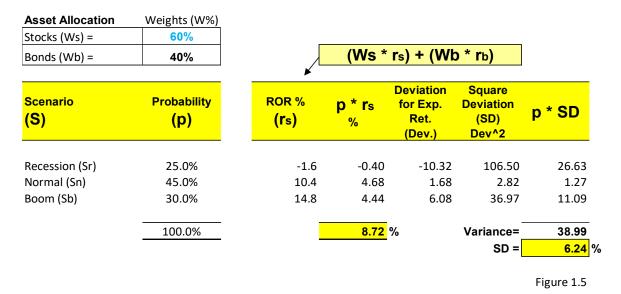

Once the return and risk are determined by asset class, the investor can achieve efficiencies and optimization (discussed in the following chapters) by allocating his or her investment across asset classes. Using the example of the stock portfolio that had return and standard deviation of 11.7% and 14.92%, respectively and the bond portfolio that had return and standard deviation of 4.25% and 8.23%, respectively, when combined at different holding levels can achieve efficiency. For argument sake, let's assume that we decided to invest 60% of our money into stock portfolio shown on figure 1.3 and 40% of our money in the bond portfolio shown on figure 1.4. then the combined portfolio consisting of 60% stock and 40% bonds shows an expected combined return, variance and standard deviation of 8.72%, 38.99% or .39x and 6.24%, respectively. As expected, as we moved from the stock portfolio of 100% to a portfolio of 60% stock and 40% bonds, the return is calculated at 8.72% measured as:

$$(Ws . Rs) + (Wb . Rb) = (.60) (11.70\%) + (.40) (4.25\%) = 7.02\% + 1.7\% = 8.72\%$$

The surprising part of this is that the standard deviation of the combined portfolio that is made of 60% stocks and 40% bonds is calculated at 6.24% which is lower that the stand-alone stock or bond portfolios' standard deviation of 14.92% and 8.23%, respectively shown in figure 1.5 below. In other words, moving from an all stock portfolio to partial stock and bonds portfolio, we achieved a greater efficiency. This phenomenon is achieved due to correlation which is basically comparing the direction of the two standard deviations. The negative correlation between the two portfolios (shown in Figure 1.6) causes the combined portfolio to have a lower standard deviation as the positive movement of the stock is offset by the negative movement of the bond resulting to a lower combined variance and standard deviation.

Insert Figure 1.5

PORTFOLIO ANALYSIS (Asset Allocation)

Of course, we arbitrary picked the 60% stock and 40% bonds that resulted to a more efficient

combined portfolio. If we continue to move the percentages around of bonds and stocks, we can eventually find the highest point of efficiency know efficient frontier. This point is examined in Chapter 2 using the same example at different correlation points. Figure 1.6 below shows that the actual correlation between the stock and bond portfolios given the standard deviations of each of the portfolios.

Setting-up the Portfolio of Stocks and Bonds - A Case Study

Assuming an asset management firm raise a new \$200 million fund called Zeus Fund I which will be set-up to buy stock and corporate bonds. In this and in next 4 chapters we will be using the Zeus Fund I as a case study apply all the tools that the portfolio analyst needs. We will also assume that the fund is leveraged at 50% - in other words, the \$200 million fund is financed by \$100 million of a loan and \$100 million of newly raised equity. Figure 1.7 below shows the transaction sources and uses of the fund. The loan is structured as a 5-year \$100 million with 5% fixed interest rate. At closing (June 1, 20x1), the \$200 million fund is used for purchasing \$82.6 million of stocks and \$96.65 million of bonds. The manager has kept about \$20mm or 10% in cash for liquidity earning 1.5% of annual interest income. The balance is used to pay accrued interest on the bonds.

HPR (UnLevered) = 12.2%

Figure 1.8

From the cash flow trading activity of this portfolio shown on Figure 1.8 above the analyst can calculate the monthly IRR – shown at 2.86%. The other return that was discussed earlier in the chapter is the Holding Period Return (HPR). For the portfolio above, the HPR is a levered HPR because 50% of capital used to finance the portfolio is by debt. The levered HPR which is HPR = $\frac{CF}{r}$ is calculated as follows (\$000 s):

$$\frac{(-100,000+3,242-1,019-831-145+513+3,277+116,347)}{100,000} = 0.214 = 21.4\%$$

The unlevered HPR is calculated as follows (\$000s):

$$\frac{(-200,000 + 3,658 - 603 - 415 + 272 + 929 + 3,694 + 216,764)}{100,000} = 0.122 = 12.2\%$$

Figures 1.9 below shows the initial purchase of the 10 stocks for \$82.6 million and bond of \$96.65 million.

Figure 1.10

Figures 1.11 and 1.11 below shows the value of the stock portfolio that includes all the trades during the hold period, as well as all the dividends received during this period. For argument sake, let's assume the manager sets-up only an 7-month trading portfolio and in order to realize return so it liquidates the entire portfolio 7 months after the initial investment (Jan 2, 20x2).

Figure 1.12

Figures 1.13 and 1.14 below shows the value of the bond portfolio that includes all the trades during the hold period including paid accrued interest, as well as all the coupon payment received during this period. For argument sake, let's assume the manager sets-up only an 7-month trading portfolio and in order to realize return so it liquidates the entire portfolio 7 months after the initial investment (Jan 2, 20x2).

Further analysis on Zeus Fund I portfolio will be shown in following chapters on this unit including, the standard deviation, Beta Coefficient Regression analysis calculations, Sharpe Ratio, Jensen's Alpha, M Square and Treynor Measures. The following chapters will also show how to achieve efficiency and optimization by trading out of stocks into bonds due to correlation as discussed earlier in this chapter.

CASE STUDY AND PRACTICE CASES

1. Based on the information below, complete the projected spreadsheet. (access spreadsheet www.professordrou.com)
